

Safe and Compliant Energization

Newly installed or modified electrical systems require a rigorous evaluation process before being energized. Acceptance testing verifies that the system meets all design specifications, industry standards, and safety codes.

HVM is a leading employer of level 3 and 4 NETA Certified technicians, and provides thorough and accurate Acceptance Testing Services.

HVM Acceptance Testing:

- Ensures quality installation.
- Supports safer startup.
- Maximizes operating efficiency.
- Enhances system integration.
- Improves the accuracy of baseline data.

Uncover Problems Before They Escalate

Acceptance testing, conducted prior to energization, offers an opportunity to uncover problems and make corrections before they escalate and become more costly. Industry studies indicate that nearly 70 percent of early electrical equipment failures can be traced back to power system design, installation, or startup deficiencies. Proactively identifying these issues through acceptance testing yields significant cost, time, and safety benefits.

The InterNational Electrical Testing Association Standard for Acceptance Testing Specifications (ANSI/NETA ATS) suggests that acceptance testing be performed by certified, independent, third parties. These qualified professionals, free from potential bias or conflicts of interest, are necessary for an objective assessment of your electrical system's functionality and adherence to code. Technicians must be both trained and experienced with the specific equipment they'll be testing and should hold industry certifications to guarantee proper testing procedures and accurate evaluation of the test results.

High Voltage Maintenance (HVM)

has a highly skilled, NETA-certified team of testing specialists and technicians with the knowledge and experience to coordinate thorough and accurate Acceptance Testing, protecting your equipment, your operational integrity, and the safety of your facility.

Common Issues Identified by Acceptance Testing:

- Incorrect Settings of Circuit Breakers and Relays
- Improper Relay Logic
- Wrong CT/PT Ratios
- Failure of Cabling
- Wrong Transformer Taps/Improper Ratios
- Compromised Insulation/Moisture Issues
- Improper Grounding
- Improperly Assembled Switchgear Bus Connections
